

Fashion stylist: how the service is built and how a request moves through it

POST /recommend takes a sentence like "an outfit for the beach this summer under \$150", plans 1 to 5 product slots with an LLM, retrieves per slot with dense + BM25 search over 100,000 indexed listings, reranks each slot with an LLM, and returns k products per slot with reasons. Solid arrows carry data, dashed arrows are LLM calls (both directions), grey boxes are files on disk, the dotted box is the only external service.

1. Offline, run once per catalog: raw json to a verified index directory

2. Online, one request: plan, retrieve, rerank, select (one deadline, every fallback reported)
